Key words: Lactobacilli, inhibition, aflatoxins, mold growth.

Abstract: The antifungal effect of five Lactobacillus strains namely L. plantarum ATCC 4008. L. plantarum 12006, Lactobacillus plantarum 299V, L. paracasei subsp. paracasei LMG 13552 and L.rhamnosus VT1was examind against some ofcommon cheese-contaminant fungi (A. parasiticus NRRL2999. versicolor, flavus Α. Penicillium roqueforti and P. communi). The ability of L. plantarum 299V, L. paracasei subsp. paracasei LMG 13552 and L. rhamnosus VT1 to inhibit aflatoxin B_1 production bv Aspergillus flavus and A. parasiticus NRRL-2999 was also studied. A11 the studied Lactobacillus strains exhibited various degrees of growth inhibition against some but not all the studied molds. The three strains of L. plantarum showed an antimycotic activity against A. versicolor and A. parasiticus but not against A. flavus.

versicolor showed the highest sensitivity toward L .rhamnosus and all of L. plantarum strains. This was followed bv parasiticus which affected at lower extent by L. plantarum strains. Growth of A. flavus was inhibited with slightly presence of L. paracasei subsp. paracasei and L.rhamnosus only. On the other hand, none of the studied Lactobacillus were found to inhibit growth of P.roauefoti or P. commune. Production of aflatoxin B_1 by A. **NRRL2999** parasiticus almost completely inhibited (98.8-99.99%) bv all investigated lactobacilli. However, the antiaflatoxigenic potential of *L. paracasei* subsp. paracasei was lower than that of L. plantarum and L. rhamnosus. The amounts of aflatoxin B_1 produced by Aspergillus flavus in the presence of these Lacobacilli were reduced by about 85-92% and 96.3-98.3% compared with control after 10 and 20 days of incubation, respectively.

Introduction

During the last few years there has been a growing interest in biopreservation, i.e., the use of microorganisms and / or their metabolites to prevent spoilage and to extent the shelf-life of foods (Stiels, 1999). Lactic acid bacteria (L A B) are of particular biopreservative interest as Their preserving organisms. effect mainly relates to the formation of lactic acid, acetic acid, and hydrogen peroxide; competition for nutrients; and the production of bacteriocins (Lindgren and Dobrogosz, 1990).

Some species of molds are intentionally used for ripening purposes in cheese production Roquefort, such as. Stilton. Camembert and Gorgonzola. Nonetheless. many of these molds are considered undesirable contaminants of cheese during storage, even at refrigeration temperatures (Cabo et al., 2002). studies Several on distribution of fungal species on cheese have shown that Penicillium is one of the most predominant genera in the fungal mycoflora of cheese (Coallier-Ascah and Idziak, 1985 and Nielson et al., 1998). Lund, et al. (1995) found that P. commune was the fungus most frequently observed in sime-hard and semicheeses collected different European countries. a high incidence Aspergillus versicolor was found in Dutch cheese warehouses between 1975 and 1980, even

though this species is not a frequent cheese contaminant (Scott, 1989). The contamination of dairy products undesirable molds, such as the genera Aspergillus and Penicillium is a serious and frequently disturbing problem because their growth can cause alteration, with the production of mycotoxins which present a potential health hazard (Filtenborg 1996). et al.. Aflatoxins are both acutely and chronically toxic to animals. including human, causing acute liver damage, liver cirrhosis. induction of tumors and teratogenic effects (Stoloff, 1977). They are produced in nature by Α. flavus. parasiticus and a recently described species A. nomius (Klich and Pitt, 1988).

Interactions between molds and different genera of LAB have been extensively described. However, the results of these studies are contradictory. While inhibition of mold growth in the of LAB has been presence by reported some authors (Karunaratne et al., 1990 and Cabo et al., 2002), a stimulatory effect of several LAB on mold growth mycotoxin and production has also been described (Suzuki et al.,1991 and Zaki et al.,1992).

The purpose of this study was to investigate (a) the ability three individual *Lactobacillus* species to inhibit growth of some commonly cheese-contaminant

molds. (b) The inhibitory effect of these bacterial cultures on aflatoxin B_1 production by the highly aflatoxin- producing strains, A.flavus and A.parasiticus NRRL2999.

Materials and Methods

Five Lactobacillus strains namely: L. plantarum **ATCC** 4008, L. plantarum 12006, Lactobacillus plantarum 299V, L. paracasei Subsp. paracasei LMG 13552 and L.rhamnosus VT1) as will as, five fungal species (A. parasiticus NRRL2999, A. flavus , versicolor, Penicillium roqueforti and P. communi) were obtained from the culture collection of the Department of Food Science and Technology at the University of Nebraska-Lincoln, USA.

Inoculation:

Frozen stock cultures of Lactic acid bacteria were prepared by thawing under optimum temperature, activated in litmus milk. Then, cultured in deMan Rogosa Sharpe (MRS) broth and incubated at 37°C for 24 h before use. The mold spore suspensions were prepared by growing the studied fungi on malt extract (Oxoid, agar Hampshire, England) slants at for 5-7 days until sporulation was observed. Spores were harvested by washing the medium surface with sterilized aqueous solution of Tween 80 (0.05% v/v). Ten ml of this solution was added to the agar

and the spores were loosened by gentle brushing with sterile spatula. Mycelia debris was removed bv filtration through sterile cheese cloth. Spore counts in the resulting suspension were determined by microscopy with hemocytometer chamber. Spore counts were finally adjusted to 10⁷ spores of each fungus per ml and stored at 4° C until use.

Antifungal activity assay:

This assay was a modification of the overlay technique described by Cabo et al. (2002). Three 10-ul drops from an active culture of each bacterial strains tested were spotted into agar plates and incubated until wellgrown colonies could observed (Ca. 48h). The plates then were overlaid with 10 ml of glucose veast extract medium (GYA), (glucose 20g / L, yeast extract 5 g / L), on which 0.1 ml of a mold spore suspension (10⁷ spores per ml) was finally spread out. After incubation for up to 5 days, the plates were examined for a halo zone formation around the bacterial colonies. These experiments were performed in triplicate.

ooAntiaflatoxigenic activity assay

The ability of three individual *Lactobacillus* species to inhibit aflatoxin B₁ production by *A. flavus* and *A. parasiticus* NRRL2999 was investigated by

the simultaneous antagonism assay as described by Munimbazi and Bullerman (1998). Hundred ml portions of glucose veast broth medium extract sterilized at 121° C for 15 min. in 250 ml Erlenmeyer flasks. Each flask was inoculated with 1 ml of fungal spores suspension containing 10⁷ spores/ ml, and 1 containing 10⁷ Cells of bacterial culture grown at 30° C for 24h in MRS medium without acetate. All flasks were incubated at 28° C and analyzed for aflatoxin B₁ production after 10 and 20 days of incubation.

Determination of aflatoxin B_1 :

At the end of the incubation period, aflatoxin \mathbf{B}_1 extracted by adding of 25 ml chloroform to each culture flask which was then shaken for 15 minutes on a wrist-action shaker. After phase separation chloroform layer was removed and the extraction repeated with additional 25 ml chloroform. Combined extracts were dehydrated over granular anhydrous sodium sulfate and evaporated to dryness at 60° C in a water bath. Residues were dissolved in 1 ml of chloroform for analysis. Aflatoxin B_1 concentration was determined by enzyme-linked immunosorbent assay (ELISA) as described by Sekhon, et al., 1996.

Results and Discussion Inhibition of fungal growth:

Results of the antimycotic activity test of three *L. plantarum* strains, as well as, one strain of each of *L. paracasei* subsp.

paracasei and L.rhamnosus against five species Aspergillus and Penicillium are summarized in Table (1). All the Lactobacillus studied strains exhibited various degrees growth inhibition against Aspergillus species. All strains of plantarum showed antimycotic activity against A. versicolor and A. parasiticus but not against A. flavus. versicolor showed the highest sensitivity toward L .rhamnosus and all of L. plantarum strains. This was followed bv parasiticus which affected at lower extent by L. plantarum strains. Growth of A. flavus was slightly inhibited with presence of *L. paracasei* subsp. paracasei and L.rhamnosus only. On the other hand, none of the studied Lactobacillus strains were found to inhibit growth of *P.roquefoti* or *P. commune*. The typical aspect of the inhibition halos is shown in Fig.1.

The inhibitory action of LAB have been demonstrated by several investigators (Corsetti et al., 1998; Coloretti, et al., 2007). Lavermicocca, et al., (2000) reported on the fungal inhibitory effects of LAB isolated from sour dough. They found that a mixture organic acids synergistically responsible for the inhibitory effect of these bacteria. . All these identified substances are low molecular weight compounds, but there are also reports of unidentified proteinaceous compounds with antifungal broad activity

(Gourama & Bullerman, 1995, 2001). 1997, Magnusson & Schnürer,

inhibition". (C) A. parasiticus NRRL2999 "weak inhibition" (D) P. roqueforti "no inhibition".

Inhibition of aflatoxin B_1 production:-

Aflatoxin B₁ production was greatly affected by the presence of a11 the investigated species. Lactobacillus Data presented in table (2) indicated that the inhibitory effect on aflatoxin B_1 production by A. parasiticus NRRL2999 ranged from 98.8% in the presence of L. subsp.paracasei paracasei

99.9% in the presence of *L. plantarum* or *L. rhamnosus* after 10 days of incubation. The toxin production was almost totally suppressed with extension of the incubation period to 20 days. The percentage of inhibition reached to 99.9 % when any of the tested bacterial culture was simultaneously grown with *A. parasiticus NRRL2999*.

Table 2: The inhibitory effect of L. plantarum, L. paracasei subsp. paracasei and L. rhamnosus on aflatoxin B_1 produced by A. parasiticus NRRL – 2999

	10 days		20 days	
Lactobacillus species	*AFB ₁ (ppm)	Inhibition (%)	*AFB ₁ (ppm)	Inhibition (%)
Control	70000		77500	
L. plantarum 299V	28	99.96	20	99.98
L.paracasei subsp.paracaseiLMG 13552	855	98.80	105	99.86
L. rhamnosus VT1	40	99.94	12	99.99

^{*} AFB₁ = Aflatoxin B₁

Results in Table (3) showed relatively lower inhibitory effect of all the three lactobacillus species against the aflatoxigenic fungus *A. flavus*.

The production of aflatoxin B₁ by A. flavus was reduced by ca. 90, 85 and 92% after 10 days of incubation and by about 97, 96 and 98% after 20 days of incubation in the presence of L. Plantarum , L. paracasei subsp.paracasei and L. rhamnosus, respectively.

Similar results have reported by other investigators. Antifungal activities by Lactobacillus species that inhibited both the growth and the production aflatoxins parasiticus has been reported by Vanne, et al. (2000) and Onilud, et al. (2005). Also, Coallier-Ascah and Idziak (1985) found that the inoculation of A. flavus culture spores into a Streptococcus lactis in synthetic broth medium resulted in little or no aflatoxin accumulation even though the growth of the fungus hindered. not was

Paracasei and L. rhamnosus on aliatoxin B_1 produced by A. flavus.

Table 3: The inhibitory effect of L. plantarum, L. paracasei subsp. Paracasei and L. rhamnosus on aflatoxin B_1 produced by A. flavus.

In conclusion, results of the present study suggest that the use of LAB offers a potential alternative as a natural foodgrade biocontrol agent of growth of cheese- contaminant molds and aflatoxin production different food commodities. Further work is needed identify and characterize active metabolites involved in the inhibition of the toxigenic Aspergilli by LAB species.
